## Load Combinations Worksheet

Show your work as you use the following load combinations to solve the problem:

## Load Combinations

1. Ultimate load $=$ dead load + live load + snow load
2. Ultimate load = dead load + live load + wind load (or earthquake load)
3. Ultimate load $=$ dead load + live load + wind load $+($ snow load $\div 2)$
4. Ultimate load $=$ dead load + live load + snow load $+($ wind load $\div 2)$
5. Ultimate load = dead load + live load + snow load + earthquake load

Calculate the five ultimate loads resulting from each combination for the following loads:
Dead load = 100,000 lbs
Live load = 30,500 lbs
Wind load = 5,020 lbs
Snow load = 400 lbs
Earthquake load $=5,000 \mathrm{lbs}$

From the five ultimate loads calculated above, for which ultimate load amount must the structure be designed?

Problem 1: Using the highest load calculated from the first page, calculate the required area of a rectangular shape made of concrete if it is a pier or a column with a compression force acting on it. If $L=10$ inches, what must $B$ be equal to?

The maximum compressive strength of this concrete is $4,000 \mathrm{lbs} / \mathrm{in}^{2}$. Use the following equations to complete the problem. Show all work and calculations.

Highest ultimate load $=$ (max. compressive strength) $x$ (cross-sectional area)
Cross-sectional area $=(\mathrm{B}) \times(\mathrm{L})$

Problem 1 cross-sectional area.

Problem 2A: Using the highest load calculated from the first page, calculate the required area of the circular shape made of concrete if it is a pier or a column with a compression force acting on it. What is the radius of this circle? The maximum compressive strength of this concrete is $5,000 \mathrm{lbs} / \mathrm{in}^{2}$.

Problem 2B: Using the highest load calculated from the first page, calculate the required cross-sectional area of the l-shape made of steel if it is a pier or a column with a tension force acting on it. The maximum tensile strength of this steel is $\mathbf{5 0 , 0 0 0} \mathrm{lbs} / \mathrm{in}^{2}$.

Use the following equations to complete the problem. Show all work and calculations.
Highest ultimate load $=$ (max. compressive strength) $\times$ (cross-sectional area)
Cross-sectional area of circle $=\pi \times$ (radius) $^{2} \quad \pi=3.14$
Highest ultimate load $=$ (max. compressive strength) $x$ (cross-sectional area)

Problem 2 cross-sectional areas.

Problem 3A: Using the highest load calculated from the first page, calculate the required $Z_{x}$ of the rectangular shape made of steel if it is a beam or a girder with a length equal to

Problem 3B: What if the same beam was made of concrete with $F_{y}$ equal to $4,000 \mathrm{lbs} / \mathrm{in}^{2}$.
Use the following equations to complete the problem. Show all work and calculations.

$$
Z_{x}=(\text { force } x \text { length }) \div\left(F_{y} \times 4\right)
$$

B

Problem 3 cross-sectional area.
