

Runaway Train!

Activity Worksheet

We will measure the speed of the toy subway car at the bottom of the incline starting at various heights along the incline.

Before you begin the experiment answer the question below:

If the train is released from anywhere on the ramp and the speed at the bottom of the incline is measured to be 5 cm/sec, what do you think the speed will be at the bottom of the incline if you **double** the height of release? Pick one:

- (a) Approximately 7 cm/sec
- (b) Approximately 10 cm/sec
- (c) Approximately 20 cm/sec

Explain your reasoning behind the prediction.

Next, complete the table below by running the experiment for 3 trials at each of the heights listed and recording the measured speed in each blank field.

Height	Trial 1 Speed	Trial 2 Speed	Trial 3 Speed
6 cm			
12 cm			
18 cm			
24 cm			

Name: _____ Date: _____ Class: _____

Compute the average speed for 6, 12, and 24 cm height

Add up the speeds for 6 cm: _____ + _____ + _____ = _____

Divide that number by 3: _____ = average speed at 6 cm

Add up the speeds for 12 cm: _____ + _____ + _____ = _____

Divide that number by 3: _____ = average speed at 12 cm

Add up the speeds for 24 cm: _____ + _____ + _____ = _____

Divide that number by 3: _____ = average speed at 24 cm

Divide the average speed for 12 cm height by the average speed for 6 cm.

What do you get? _____

Now divide the average speed for 24 cm by the average speed for 12 cm.

What do you get? _____

Divide the average speed for 24 cm by the average speed for 6 cm.

What do you get? _____

When does the train have the most potential energy? _____

When does the train have the least potential energy? _____

When does the train have the most kinetic energy? _____

When does the train have the least kinetic energy? _____

What connection can you make between potential energy and kinetic energy for the train?

Conclusion: Write 1-2 sentences about the relationship between speed and start height of the train that you observed. Was your prediction correct?
